CS 188 Fall 2007

Introduction to Artificial Intelligence

Midterm Solutions

You have 80 minutes. The exam is closed book, closed notes except a one-page crib sheet, basic calculators only. 80 points total. Don't panic!

Mark your answers ON THE EXAM ITSELF. Write your name, SID, login, and section number at the top of each page.

For true/false questions, CIRCLE True OR False.

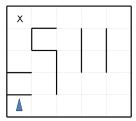

If you are not sure of your answer you may wish to provide a *brief* explanation. All short answer sections can be successfully answered in a few sentences at most.

1. (18 points.) True/False

- (a) True/False: If one search heuristic $h_1(s)$ is admissible and another one $h_2(s)$ is inadmissible, then $h_3(s) = \min(h_1(s), h_2(s))$ will be admissible.
- (b) True/False: Greedy search has the same worst-case number of node expansions as DFS.
- (c) True/False: In A*, the first path to the goal which is added to the fringe will always be optimal.
- (d) True/False: If a CSP is arc consistent, it can be solved without backtracking.
- (e) True/False: A CSP with only binary constraints can be solved in time polynomial in n and d, the number of variables and size of the domains.
- (f) True/False: The minimax value of a state is always less than or equal to the expectimax value of that state.
- (g) True/False: Alpha-beta pruning can alter the computed minimax value of the root of a game search tree.
- (h) *True/False*: When doing alpha-beta pruning on a game tree which is traversed from left to right, the leftmost branch will never be pruned.
- (i) *True/False*: Every search problem can be expressed as an MDP with at most as many states as the original search problem.

2. (18 points.) Search and Heuristics

Imagine a car-like agent wishes to exit a maze like the one shown below:

The agent is directional and at all times faces some direction $d \in (N, S, E, W)$. With a single action, the agent can either move forward at an adjustable velocity v or turn. The turning actions are left and right, which change the agent's direction by 90 degrees. Turning is only permitted when the velocity is zero (and leaves it at zero). The moving actions are fast and slow. Fast increments the velocity by 1 and slow decrements the velocity by 1; in both cases the agent then moves a number of squares equal to its NEW adjusted velocity. Any action which would collide with a wall crashes the agent and is illegal. Any action which would reduce v below 0 or above a maximum speed V_{max} is also illegal. The agent's goal is to find a plan which parks it (stationary) on the exit square using as few actions (time steps) as possible.

As an example: if the agent shown were initially stationary, it might first turn to the east using (right), then move one square east using fast, then two more squares east using fast again. The agent will of course have to slow to turn.

(a) (3 points) If the grid is M by N, what is the size of the state space? Justify your answer. You should assume that all configurations are reachable from the start state.

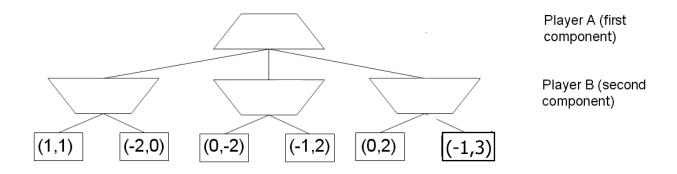

- (b) (2 points) What is the maximum branching factor of this problem? You may assume that illegal actions are simply not returned by the successor function. Briefly justify your answer.
- (c) (3 points) Is the Manhattan distance from the agent's location to the exit's location admissible? Why or why not?

3. (16 points.) Game Search

The standard Minimax algorithm calculates worst-case values in a zero-sum two player game, i.e. a game in which for all terminal states s, the utilities for players A (MAX) and B (MIN) obey $U_A(s) + U_B(s) = 0$. In the zero sum case, we know that $U_A(s) = -U_B(s)$ and so we can think of player B as simply minimizing $U_A(s)$.

In this problem, you will consider the *non zero-sum* generalization in which the sum of the two players' utilities are not necessarily zero. Because player A's utility no longer determines player B's utility exactly, the leaf utilities are written as pairs (U_A, U_B) , with the first and second component indicating the utility of that leaf to A and B respectively. In this generalized setting, A seeks to maximize U_A , the first component, while B seeks to **maximize** U_B , the second component.

- (a) (4 points) Propagate the terminal utility pairs up the tree using the appropriate generalization of the minimax algorithm on this game tree. Fill in the values (as pairs) at each of the internal node. Assume that each player maximizes their own utility. *Hint:* just as in minimax, the utility pair for a node is the utility pair of one of its children.
- (b) (2 points) Briefly explain why no alpha-beta style pruning is possible in the general non-zero sum case. Hint: think first about the case where $U_A(s) = U_B(s)$ for all nodes.

4. (15 points.) MDPs and Reinforcement Learning

In Flipper's Folly, a player tries to predict the total number of heads in two coin flips. The game proceeds as follows (also shown below):

- (a) From the start state (XX), choose the special action begin (only possible action)
- (b) Flip a coin and observe the result, arriving in the state HX or TX
- (c) Guess what the total number of heads will be: $a \in \{0, 1, 2\}$
- (d) Flip a coin and observe the result, arriving in one of the states HH, HT, TH, TT.
- (e) Count the total number of heads in the two flips; $c \in \{0, 1, 2\}$
- (f) Receive reward $R(s, a, s') = \begin{cases} 2 \cdot a^2 c^2 & \text{if } c \ge a \\ -3 & \text{if } c < a \end{cases}$ where c is the total number of heads in s'

Note that the rewards depend only on the action and the landing state, and that all rewards for leaving the start state are zero. The MDP for this game has the following structure, where all legal transitions have probability $\frac{1}{2}$. Assume a discount rate of 1.

| NAME: | SID#: | Login: | Sec: | 7 |
|-------|-------|--------|------|---|
|-------|-------|--------|------|---|

- (a) (3 points) What is the value of the start state under the policy of always guessing a = 2?
- (b) (5 points) Run value iteration on this MDP until convergence. *Hint*: values and q-values of terminal states are always 0.

| | $V_k^*(s)$ | | | | |
|------------------|------------|----|----|--|--|
| k | XX | HX | TX | | |
| 0 | 0 | 0 | 0 | | |
| 1 | | | | | |
| 2 | | | | | |
| 3 | | | | | |
| 2 3 4 5 | | | | | |
| 5 | | | | | |

- (c) (2 points) What is the optimal policy for this MDP?
- (d) (5 points) Run q-learning in this MDP with the following (s, a, s', r) observations. Use a learning rate of $\frac{1}{2}$. Leave zero entries blank.

| | | | | | | (| Q(s,a) | | | |
|----|-------|----|----|------------|--------|--------|--------|--------|--------|--------|
| s | a | s' | r | (XX,begin) | (HX,0) | (HX,1) | (HX,2) | (TX,0) | (TX,1) | (TX,2) |
| | | | | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| XX | begin | HX | 0 | | | | | | | |

| XX | begin | HX | 0 | | | | | | | |
| HX | 2 | НН | 4 | | | | | | | |
| XX | begin | HX | 0 | | | | | | | |

| 5. | (13 points.) Short Answer Each question can be answered in a single sentence! |
|----|--|
| | (a) (2 pts) For A* search, why might we prefer a heuristic which expands more nodes over one which expands fewer nodes? |
| | (b) (2 pts) Why is minimax less reasonable than expectimax as a practical decision-making principle for a complex agent acting in the real world? |
| | (c) (4 pts) An agent prefers to be given an envelope containing \$4 rather than one containing either \$0 and \$10 (with equal probability). Give a justification for how the agent could be acting in accordance with the principle of maximum expected utility. |
| | (d) (4 pts) A stochastic policy π is one which does not recommend a single, deterministic action for each state s , but rather gives each possible action a a probability. Let $\pi(s,a)$ be the probability that the policy assigns to action a from state s . State a one-step lookahead Bellman equation for $V^{\pi}(s)$ for the case of stochastic policies π . |

(e) (3 pts) Under what conditions can an MDP be solved using standard state space search techniques (DFS, BFS, etc.)?
