CS 70 Discrete Mathematics for CS Spring 2005 Clancy/Wagner — MT 1 Soln

Problem 1. [True or false] (12 points)

(a) TRUE or **False**: The propositions $P \implies Q$ and $Q \implies P$ are logically equivalent.

(Converse error.)

(b) **True** or FALSE: The proposition $Q \vee P \vee (P \implies Q)$ is guaranteed to be true, no matter what the truth values of P and Q may be.

(Equivalent to $Q \vee P \vee (\neg P \vee Q)$.)

(c) TRUE or **False**: If we are told that the proposition P is true, we are entitled to conclude that $((P \implies Q) \implies P) \implies Q$ must also be true.

(Try $Q =$ false.)

(d) **True** or FALSE: $\forall n \in \mathbf{N} \,.\, (x^2 - x = 0) \vee (x \geq 2)$.

(True for $x = 0, 1, 2, \ldots$)

(e) TRUE or **False**: $\forall x \in \mathbf{N} \,.\, \exists y \in \mathbf{N} \,.\, \forall z \in \mathbf{N} \,.\, x + y = z$.

(Counterexample: $z = x + y + 1$.)

(f) **True** or FALSE: $\forall x \in \mathbf{N} \,.\, \exists y \in \mathbf{N} \,.\, x^2 = y$.

(y is allowed to depend on x, since it appears on the inside.)

(g) TRUE or **False**: $(\forall x \in \mathbf{N} \,.\, \exists y \in \mathbf{N} \,.\, x < y) \equiv (\exists y \in \mathbf{N} \,.\, \forall x \in \mathbf{N} \,.\, x < y)$.

(Not logically equivalent: the left-hand side is true, but the right-hand side is false.)

(h) **True** or FALSE: Let $P(n)$ denote the proposition that $1 + 2 + \cdots + n + (n+1) = n(n+1)/2$. Then $\forall n \in \mathbf{N} \,.\, P(n) \implies P(n+1)$ is true.

($P(n) =$ false for all $n \in \mathbf{N}$, so the implication is of the form "false $\implies$ false".)

(i) **True** or FALSE: Define the relation $\prec$ so that $n \prec m$ iff n divides m and $n < m$. Then the relation $\prec$ is a well-ordering on $\mathbf{N}$.

(Any subset of $\mathbf{N}$ has a minimal element under $\prec$: its smallest element will be minimal.)

(j) **True** or FALSE: Any 2-party cake-cutting protocol that is fair is also envy-free.

(If Alice receives $x \geq \frac{1}{2}$ of the cake, then Bob receives $1 - x \leq \frac{1}{2} \leq x$.)

(k) TRUE or **False**: In the stable marriage problem, if M denotes the male-optimal matching, then there exists a girl who does not get her optimal boy in M (i.e., her mate in M is not her optimal boy).

(If b_i lists g_i as his top choice, and vice versa, then there is only one stable pairing; it is simultaneously male- and female-optimal.)

(l) TRUE or **False**: Suppose that we have n boys, $b_1, \ldots, b_n$, and n girls, $g_1, \ldots, g_n$. Assume that g_1 lists b_1 as her top choice, g_2 lists b_2 as her top choice, and so on, so that b_i appears at the front of g_i's preference list for all i. If we run the Traditional Marriage Algorithm, then the resulting matching is guaranteed to match g_i to b_i for all i.

(Let $n = 2$, b_1 likes g_2 best, b_2 likes g_1 best; then TMA gives the boys their top choices, but not the girls.)

Problem 2. [A peculiar sequence] (6 points)

Define $u_0 = u_1 = 1$, and define $u_n = (n-1)u_{n-2}$ for $n = 2, 3, 4, \ldots$. By convention, $0! = 1$.

Prove that $u_{n+1}u_n = n!$ for all $n \in \mathbf{N}$.

Proof by simple induction on n, with the predicate $P(n) =$ "$u_{n+1}u_n = n!$".

Base case: For $n = 0$, we have $u_1u_0 = 1 = 0!$.

Inductive step: Assume $u_{n+1}u_n = n!$. Then, by the definition of u_{n+2}, we have $u_{n+2} = (n+1)u_n$ (since $n+2 \geq 2$). Moreover,

$$\begin{aligned} u_{n+2}u_{n+1} &= (n+1)u_{n-1}u_n \\ &= (n+1)\,n! && \text{(by the inductive hypothesis)} \\ &= (n+1)! \end{aligned}$$

Therefore $P(n) \implies P(n+1)$ for all $n \in \mathbf{N}$, so the claim follows by induction.

Problem 3. [Recognizing complete binary trees] (6 points)

A *binary tree* is a tree with the property that every internal node (i.e., every non-leaf node) has exactly two children. A binary tree is called *complete* if all its leaves are at the same depth.

Assume that if `T` is a tree, then the helper function `(leaf? T)` returns true iff `T` has no children. Also, if `T` is a tree with children, then `(left T)` returns the left subtree of `T` and `(right T)` returns the right subtree of `T`. Consider the following algorithm:

```
(define (complete? T)
    (if (leaf? T)
      #t
      (and (complete? (left T)) (complete? (right T))) ) )
```

Here is an attempt to prove this algorithm correct.

Theorem 0.1: *For all trees T, if* `(complete? T)` *returns true, then there exists* $k \in \mathbf{N}$ *such that every leaf is at distance k from the root of T.*

Proof: Use proof by structural induction. Base case: Suppose the tree `T` has no children, so that `(leaf? T)` returns true. Then `(complete? T)` also returns true, and moreover every leaf is at distance 0 from the root (i.e., $k = 0$), so the implication is true in this case.

Inductive step: Assume the claim is true for trees `TL` and `TR`. Suppose the tree `T` is constructed so that the left subtree of the root is `TL`, and the right subtree is `TR`. Assume `(complete? T)` returns true. By the definition of `(complete? T)`, this means that `(complete? TL)` and `(complete? TR)` must both have returned true. Then, by the induction hypothesis, there is some k so that every leaf of `TL` is at distance k from the root of `TL`. Similarly, there is some k so that every leaf of `TR` is at distance k from the root of `TR`. In both cases, the leaf is at distance $k+1$ from the root of `T` (by the way that `T` was constructed from `TL` and `TR`). Also, every leaf of `T` falls into one of these two cases. Consequently, we have proven that if `(complete? T)` returns true, then there exists $k' \in \mathbf{N}$ so that every leaf of `T` is at distance k' from the root of `T` (in fact, $k' = k+1$). □

Please tell us whether this proof is valid. In particular, answer each of the following questions with "Yes" or "No", and explain your answer:
(a) Is the use of structural induction appropriate?

Yes. Structural induction is a fine way to prove that something is true for all binary trees.

(b) Is the proof of the base case ok?

Yes. The base case is indeed a tree with just one node.

(c) Is the proof of the inductive step ok?

No! It is true that every leaf of `TL` *is at distance* k_L *from the root of* `T`*, for some* k_L*, and likewise every leaf of* `TR` *is at distance* k_R *from the root—but there is no guarantee that* $k_L = k_R$*.*

(d) Bottom line: Is the proof valid?

No. The inductive step is wrong. In fact, the claim is false: `complete? T` *might return true on an input that is not a complete tree.*

Problem 4. [Working with expressions some more] (8 points)

This question involves expressions generated by the following rules. (Note that rule 2. is slightly different from what you saw on a previous quiz.)

1. A single digit is an expression.
2. If E_1 and E_2 are expressions, then E_1E_2 is an expression.
3. If E is an expression, then (E) is an expression.

Prove that no expression generated by the three rules above contains an open parenthesis immediately followed by a close parenthesis, i.e. "()".

Proof by strong induction on the number of applications of the rules. Let $P(k)$ ="for every expression E generated using exactly k applications of the above rules, E contains no (), E does not start with), E does not end with (, and E is not empty".

Base case: For $k = 1$, the only way to get an expression is by application of rule 1. A single digit contains no parentheses, so it contains (), does not start with), does not end with (, and is not empty.

Inductive step: Suppose $P(1) \wedge \cdots \wedge P(k)$ is true, i.e., every expression generated using at most k rule-applications has no (), doesn't start with), end with (, and isn't empty. We will prove that $P(k+1)$ is true. Let E denote any expression generated using exactly $k+1$ rule-applications. There are three cases, divided into which rule was used in the $k+1$th rule-application:

1. If the last rule was Rule 1.: E is a single digit, so it contains no (), doesn't start with) or end with (, and is non-empty.
2. If the last rule was Rule 2.: $E = E_1E_2$ for some expressions E_1 and E_2. E_1 must have been generated using at most k rule-applications and thus (by the inductive hypothesis) has no (), doesn't end in (, and is non-empty. Likewise, E_2 has no (), doesn't start with), and is non-empty. It follows that the concatenation E_1E_2 has no (), by considering where a (could occur (anywhere in E_1 except the last symbol, and anywhere in E_2) and using the fact that neither E_1 nor E_2 has (). Moreover, E_1E_2 doesn't start with) (since E_1 doesn't, and is non-empty), doesn't end with ((since E_2 doesn't, and is non-empty), and E_1E_2 is non-empty (since E_1 is non-empty).
3. If the last rule was Rule 3.: $E = (E_1)$, for some expression E_1. E_1 must have been generated using at most k rule-applications and thus (by the inductive hypothesis) has no (), doesn't end in (or start with), and is non-empty. It follows that (E_1) has no (): the first (in (E_1) is not immediately followed by a) (since E_1 is non-empty); and any other (in (E_1) is not immediately followed by a), since such a (must occur in E_1, not at the end of E_1, and thus cannot be immediately followed by a). Moreover, (E_1) does not start with) or end with (, and is not empty.

Alternate approach: You could have used $P(k)$ = "no expression generated with k rule-applications contains a ()", and then proved a separate Lemma stating that no expression starts with), ends with (, or is empty. Such a Lemma could also be proved using strong induction.

Common errors:

- Many answers started from an example of something that would be bad, and then tried to prove it couldn't happen. (What about other bad things?)

  Some people tried to argue that () is not an expression, and stopped there. But that is not enough: you had to show that no expression contained () as a substring.

- Converse errors were common. Example: "Suppose $E = (E_1)$ is an expression. Then E_1 must be an expression." — wrong. (Counterexample: $E = (1)(2)$.)

  Some answers tried starting with an expression and 'breaking it down', but such proofs usually failed to justify why you can 'break an expression down' and often succumbed to converse errors.

- Many people failed to state what induction predicate $P(n)$ they were using, or what kind of induction they were using (simple? strong? structural? infinite descent?).

- If you use induction on the number of rules, you need to use strong induction. Suppose E was generated using $k+1$ rule-applications, and $E = E_1E_2$ (by Rule 2.). You need to take into account the possibility that E_1 and E_2 were generated with strictly less than k rule-applications.

- Many proofs did a case analysis of how some expression could arise, but failed to check that the cases covered all possibilities. Example: "Let E be an expression of size $n+1$. The only way to get E out of an expression of size n is by ..." (What if there is some other way to get E? For instance, what if E is built out of an expression E_1 of size 2 and an expression E_2 of size $n-2$?)

- Some people noticed that we need the fact that no expression starts with), ends with (, or is empty— but then asserted this without proof. Recognizing this subtlety is good, but you also need to prove that this invariant holds (e.g., by induction).

- A common error was to assert that the induction hypothesis applies without explaining why. A rarer error was to assume what was to be proven. Example: "Let $P(k) =$ 'no expression with k digits contains a ()'. To show: $P(k) \implies P(k+1)$. Consider any expression $E = (E_1)$ with $k+1$ digits. By the induction hypothesis, E_1 contains no (), therefore..." — bogus. (E_1 has $k+1$ digits, so you need to assume $P(k+1)$ to prove $P(k+1)$.)

- Example: "Rule 3. is the only rule that adds parentheses, so no expression can start with) [or, contain (), or ...]." (Fails to consider the possibility that some other rule might introduce the forbidden string without adding any new parentheses. For instance, maybe Rule 2. takes a) and moves it to the front. It doesn't, but this could use justification.)

- Some people tried using predicates that make induction too hard. Example: "Let n = the number of applications of Rule 3." (Base case becomes non-trivial: there are infinitely many expressions formed without any use of Rule 3.) Example: "Let n = the number of digits." (The induction step becomes too hard, because we could apply Rule 3. many times without changing n.)

Stylistic advice on good proofs:

- All variables in a proof should be immutable. Don't try changing the meaning of a variable. Example: "We start with E, and we add parentheses surrounding it, and afterwards E still contains no ()."

- Be wary of type errors. Example: "The expression $P(n)$ has no ()." — wrong. ($P(n)$ is a boolean proposition, not an expression.)
- If you haven't used the induction hypothesis anywhere in your proof, that is suspicious.

Problem 5. [A variant on merge sort] (8 points)

Let F_k denote the kth Fibonacci number. Reminder: the Fibonacci numbers are defined by $F_0 = F_1 = 1$, and $F_k = F_{k-1} + F_{k-2}$ for $k \geq 2$. Consider the following variation on merge sort, which assumes that the number of elements in its list argument L is a Fibonacci number F_k.

```
algorithm FibMergesort(L)
{L is a list of items from a totally ordered set, whose length is a Fibonacci number F_k}
if L contains only 1 element, then return L
else
   divide L into L_1 (the first F_{k-1} items) and L_2 (the remaining F_{k-2} items)
   sortedL_1 := FibMergesort(L_1)
   sortedL_2 := FibMergesort(L_2)
   sortedL := Merge(sortedL_1, sortedL_2)
   return sortedL
```

Assuming that the "divide" step in FibMergesort takes constant time (no comparisons) and Merge behaves as described in the lecture notes, identify which of the following expressions most closely matches the total number of comparisons performed by FibMergesort when initially given a list of F_k elements.

(a) $\mathbf{O}(k \log k)$

(b) $\mathbf{O}(k^2)$

(c) $\boxed{\mathbf{O}(k\,F_k)}$

(d) $\mathbf{O}(F_k \log k)$

(e) $\mathbf{O}(F_k^2)$

The depth of the recursion tree is $k-1$. The total number of comparisons done at each level of the tree is at most F_k, since the size of the lists at each level sum to F_k, and the number of comparisons used by Merge is no more than the total list size. (In fact, we do strictly less than F_k comparisons at the bottom $k/2$ levels, but that's OK.) Thus the total number of comparisons is the number of levels times the number of comparisons done per level, or $\mathbf{O}(k\,F_k)$.

Alternate answer: Let $T(k) =$ the number of comparisons performed by FibMergesort on an input list of size F_k. Then $T(k) = T(k-1) + T(k-2) + F_k - 1$ (since Merge uses $F_k - 1$ comparisons to merge two lists of total size F_k), and $T(1) = T(0) = 0$.

Claim: $T(k) \leq k\,F_k$ for all k.

Proof: By strong induction on k. Base cases: $T(0) = 0 \leq 0 \cdot 1$ and $T(1) = 0 \leq 1 \cdot 1$. Inductive step: Assume it is true for $k-1$ and $k-2$. Then

$$\begin{aligned} T(k) &= T(k-1) + T(k-2) + F_k - 1 \\ &\leq (k-1)F_{k-1} + (k-2)F_{k-2} + F_k - 1 && \text{(by the inductive hypothesis)} \\ &\leq (k-1)F_{k-1} + (k-1)F_{k-2} + F_k \\ &\leq (k-1)F_k + F_k \leq k\,F_k. \end{aligned}$$

□
